

margo version

Purpose

`margo version` prints release identity and capabilities compiled into the binary.

`margo --version` is an exact alias. Neither form searches for a browser or probes an external engine.

Input and output

The command accepts no input. Its text report goes to stdout and includes the Margo version, module, commit, Go version, platform, compiled engines, and a reminder to run `doctor` for external discovery. Argument errors go to stderr.

Examples

```
margo version > build/margo-version.txt  
cat build/margo-version.txt
```

```
margo --version
```

Failures and diagnostics

Extra positional arguments use Cobra's text error and exit `1`. A successful report exits `0`; there are no command-specific numeric exit codes.

Limitations and care

A source build can report `dev`, `unknown`, and `compiled engines none`; those values describe build metadata, not whether Chromium is installed. Use `margo doctor` to inspect external engine candidates.
